The aim of the study was to examine the effects of rubber compounds of different curing rates (5, 7, and 10 min) and environmental temperature (21, 37, and 55 degrees C) on the stress-strain behavior of the flexural bar of a stainless steel molar (diameter 30 mm, height 9 mm, and working length 20 mm). The data were analyzed by means of X-ray diffraction analysis, polarization microscopy, scanning electron microscopy, and the dynamic mechanical analysis. When the curing rate was increased, the mechanical properties of the silica-modified ethylene-propylene rubber (EPR) materials improved. However, as the curing time increased to 10 min, the mechanical properties of the EPR materials became less. The environmental temperature also had a significant effect. The characteristic elongation increased and the limiting strength and limiting extension decreased with increasing temperature. The decrease in strength was not as high as the shrinkage had caused because the anisotropy of the flexural bar was relatively low.Fruit and vegetable intake is modestly associated with risk of multiple chronic diseases in the general population: results from the EPIC-PANACEA Study.
